## ABSTRACT

---

Sequence alignment is the process of detecting similarities between biological sequences, such as DNA, RNA and proteins. For the last half a century, sequence alignment has been of central importance for molecular biology. Applications include evolutionary biology, genome assembly, read mapping, variation detection. Computational methods are crucial for the correctness of the analyses of the vast amounts of biological data. Can we use the A\* algorithm to find optimal alignments fast?

This thesis explores two variations of the alignment problem: *reads mapping* and *pairwise alignment*, also known as semi-global and global alignment. Biological sequences do not generally align perfectly due to biological differences and technical errors. Given two sequences, the desired alignment is a position-to-position correspondence between two sequences which minimizes the edit costs (substitutions, insertions or deletions). This task is closely related to calculating *edit distance*. Practical alignment algorithms are desired to ① find accurate alignments, ② apply to a wide range of data, and ③ use little time and memory.

Existing aligning algorithms are either optimal but quadratic or fast but approximate. Even though the resulting alignment is linear. This gap has motivated the development of various faster but approximate algorithms. Moreover, theoretical results suggest that it is that in general, alignment is not solvable in strongly subquadratic time.

We consider a principled shortest path formulation of alignment and argue that the A\* algorithm fulfills the desired properties better than current methods. In this thesis we argue that the A\* informed search algorithm radically improving the runtime scaling (up to linear) in the average case while can provide optimality guarantees while. On real data, this approach reaches orders of magnitude of speedup compared to existing approaches.

An optimal alignment can naturally be represented as a shortest path in an alignment graph (equivalent to the DP table). In order to find such a shortest path with minimal exploration, we instantiate the A\* algorithm with a novel problem-specific heuristic function based on the unaligned parts of the sequences. This additional information is a problem-specific heuristic function and it heavily determines the efficiency of the search. For any explored state by A\*, this heuristic function should compute a lower

bound on the remaining path length, or more specifically, the minimal cost of edit operations needed to align the remaining sequences.

Seed heuristic. In practice, while achieving polynomial speed ups on real data. It ① provides optimality guarantees according to edit distance, ② scales to long and noisy sequences, and ③ scales subquadratically with sequence length. To scale to large reference sequences, we extend the graph with a trie index. To scale to long queries, we introduce design an admissible *seed heuristic*, which is provably-optimal also efficient to compute. To scale to high error rates, we design

Many tools do not have a well-stated problem they optimize.

Probabilistic approach. Focus on the metric. Extend to MSA, local, affine. Prototype implementations No asymptotics.

### FREQUENTLY USED SYMBOLS

$E$  energy

$m$  rest mass

$p$  impulse

### PHYSICAL CONSTANTS

$c$  speed of light in vacuum,  $c = 299\,792\,458\,\text{m s}^{-1}$

(CODATA 2014 [1])

## INTRODUCTION

---

*It is better to be wrong than to be vague.*

— Freeman Dyson

The number of possible alignments grow exponentially with length. The usual underlying question to finding “correct” alignments. Regarding the precision of alignment, one is usually interested in base-to-base (aka letter-to-letter) correspondence between the sequences, even though for some applications a less detailed solution is sufficient: only the similarity between sequences or the location where a read maps to a reference. Exact alignment is only useful for very short sequences (often kmers), and for all other cases the optimized metric may be hamming distance, edit distance (unit costs), Levenshtein distance, affine costs, convex and concave costs, general costs and others.

Depending on the the number of aligned sequences, there is pairwise alignment and multiple sequence alignment (MSA). Depending on the parts of the sequences that are aligned to each other, we differentiate global, local and various semi-global alignemnts. There are generalizations to sequence-to-sequence alignment, including aligning to nonlinear structures, such as directed acyclic graphs, DAGs, general graphs and others. These structures are nowadays becoming more common as a compressed form of representing a set of references to which a sequence can be aligned. Often, one best alignment is sufficient but finding several best (top-K) alignments. In the context of read mapping, a set of reads is aligned to the same reference sequence so an indexing procedure is often useful for the performance.

We specifically consider the mapping of a set of reads to a general graph, and the global pairwise alignment.

Existing optimal algorithms are based on dynamic programming (DP) and run in quadratic time (assuming that the number of errors is proportional to the length)

we employ the  $A^*$  algorithm which is an *informed* algorithm,

## SAMPLE CHAPTER

*The true logic of this world is in the calculus of probabilities.*

— James C. Maxwell

Maxwell [2] derived some very useful equations for electromagnetic fields:

$$\nabla \cdot \vec{D} = \rho \quad (2.1)$$

$$\nabla \cdot \vec{B} = 0 \quad (2.2)$$

$$\nabla \times \vec{E} = -\frac{\partial \vec{B}}{\partial t} \quad (2.3)$$

$$\nabla \times \vec{H} = \vec{j} + \frac{\partial \vec{D}}{\partial t} \quad (2.4)$$

The energy-momentum relation, eq. (2.5), is one of *my* important results:

$$E^2 = m^2 c^4 + (pc)^2 \quad (2.5)$$

Write units like this: 5  $\mu\text{m}$ .

FIGURE 2.1: A lovely face.

## HEADING ON LEVEL 0 (CHAPTER)

---

Hello, here is some text without a meaning. This text should show what a printed text will look like at this place. If you read this text, you will get no information. Really? Is there no information? Is there a difference between this text and some nonsense like “Huardest gefburn”? Kjift – not at all! A blind text like this gives you information about the selected font, how the letters are written and an impression of the look. This text should contain all letters of the alphabet and it should be written in of the original language. There is no need for special content, but the length of words should match the language.

### 3.1 HEADING ON LEVEL 1 (SECTION)

Hello, here is some text without a meaning. This text should show what a printed text will look like at this place. If you read this text, you will get no information. Really? Is there no information? Is there a difference between this text and some nonsense like “Huardest gefburn”? Kjift – not at all! A blind text like this gives you information about the selected font, how the letters are written and an impression of the look. This text should contain all letters of the alphabet and it should be written in of the original language. There is no need for special content, but the length of words should match the language.

This is the second paragraph. Hello, here is some text without a meaning. This text should show what a printed text will look like at this place. If you read this text, you will get no information. Really? Is there no information? Is there a difference between this text and some nonsense like “Huardest gefburn”? Kjift – not at all! A blind text like this gives you information about the selected font, how the letters are written and an impression of the look. This text should contain all letters of the alphabet and it should be written in of the original language. There is no need for special content, but the length of words should match the language.

And after the second paragraph follows the third paragraph. Hello, here is some text without a meaning. This text should show what a printed text will look like at this place. If you read this text, you will get no information.

Really? Is there no information? Is there a difference between this text and some nonsense like “Huardest gefburn”? Kjift – not at all! A blind text like this gives you information about the selected font, how the letters are written and an impression of the look. This text should contain all letters of the alphabet and it should be written in of the original language. There is no need for special content, but the length of words should match the language.

After this fourth paragraph, we start a new paragraph sequence. Hello, here is some text without a meaning. This text should show what a printed text will look like at this place. If you read this text, you will get no information. Really? Is there no information? Is there a difference between this text and some nonsense like “Huardest gefburn”? Kjift – not at all! A blind text like this gives you information about the selected font, how the letters are written and an impression of the look. This text should contain all letters of the alphabet and it should be written in of the original language. There is no need for special content, but the length of words should match the language.

## CURRICULUM VITAE

---

### PERSONAL DATA

Name	Albert Einstein
Date of Birth	March 14, 1879
Place of Birth	Ulm, Germany
Citizen of	Switzerland

### EDUCATION

1896 – 1900	Eidgenössisches Polytechnikum, Zürich, Switzerland <i>Final degree:</i> Diploma
1895 – 1896	Aargauische Kantonsschule (grammar school) Aarau, Switzerland <i>Final degree:</i> Matura (university entrance diploma)
– July 1894	Luitpold-Gymnasium (grammar school) Munich, Germany

### EMPLOYMENT

June 1902 –	Technical Expert, III Class <i>Federal Office for Intellectual Property,</i> Bern, Switzerland
-------------	--
